

Re-Engineering of the Damaged Brain and Spinal Cord: Evidence-Based Neurorehabilitation (Acta Neurochirurgica Supplement) (Pt. 2)

Re-Engineering of the Damaged Brain and Spinal Cord is dedicated to Tetsuo Kanno, M. D., Professor of Neurosurgery. By presenting the original papers that make up this feature of the local medical landscape in the third supplement we wish to make a further contribution to the issue of functional rehabilitation, this gives new findings must be also subjected to a frequent so important and fascinating modern area of research. Onto of this, it should not be forgotten that in the field of neurosciences. The congress papers we even when committal therapy guidelines are chosen have selected constitute a good reflection of the consistently applied, there are considerable variations in disciplinary objectives. The literature references are the range of potential complications and in the designed as a guide to lead the interested reader to come of prospective controlled multi-centre and deeper and more detailed understanding of the national studies on the issue of quality management. Functional rehabilitation has been an original task. The demand for evidence-based medicine is well of neurosurgery from the very outset. The 1990s have justified; however, it rapidly comes up against the entered the annals of brain research as the decade of limits of feasibility, especially where controlled the Brain. Since then there has been an ever stronger peptic studies are concerned. The Cochrane collection growth of neuroscientist interest worldwide, accom of high-quality evidence-based healthcare databases

panied by substantial financial engagement. This has thus far been of no help to us in drawing up the - primarily resulted in advances in basic neuro- peutic recommendations for the re-engineering of biological and neurophysiological research and also in brain and spinal-cord lesions. Today as ever, the the growth of neuroscienti? knowledge about basic opinion of experts and empirically based medical mechanisms for motor control, pain control, aware- treatment and posttraumatic neurorehabilitation ness, cognition, learning and memory. The conse- continue to occupy an indispensable position for the quence must be to ensure that the advances made in the everyday clinical practice of neurosurgical and neu- neuroscienti? research are adequately expanded traumatological therapies. Promising adjunct - into practical neurosurgical care and re-engine ering of proaches include neuropharmacology, for cascades of brain and spinal cord lesions and to ensure upon new molecular interactions are known to be underlying approaches. Following this a fundamental path will activity-dependent plasticity and skills learning, as result in an improved and more efficient prevention in many of these processes involve the major tra- the future, the measures that stand right at the fore- mitters. Furthermore, biological interventions by- front of all rehabilitation principles, meaning that in endogenous neurons and glia as well as exogenous conventional concepts must be modified to keep pace stem cells, bone-marrow cells, macrophages, and other with the more task-speci?c, intensive, and progressive types may promote the regeneration of nerve cells, demands. In this connection a series of guidelines, tissue, and neural circuitry. Class one

studies have recommendations, and expert opinions and also been made, and now class two studies have been identified, algorithms have been elaborated by national and international, for example in connection with acute spinal cord injury (SCI). The clinical application of expert panels and multidisciplinary assessment and treatment of SCI. The clinical application of expert panels and multidisciplinary assessment and treatment of SCI. The clinical application of expert panels and multidisciplinary assessment and treatment of SCI.
